- Externalizing Resources

- Content From Textbook:

Professional Android by Reto Meier and Ian Lake

Published by John Wiley and Sons Inc.,
2018

Today's Lecture

- It is good practice to keep non-code resources external to your code.
- Examples of non-code resources:
 - Images
 - String constants
- Easier to maintain, update, and manage.
- Makes it easy to define alternative resources.

Externalizing Resources

- **Dynamic Selection.** Android dynamically selects resources from resource trees that contain different values for alternative hardware configurations, languages, and locations.
- When an application starts Android automatically selects the correct resources without you having to write a line of code.
- You just have to define the resources for each situation.

Externalizing Resources

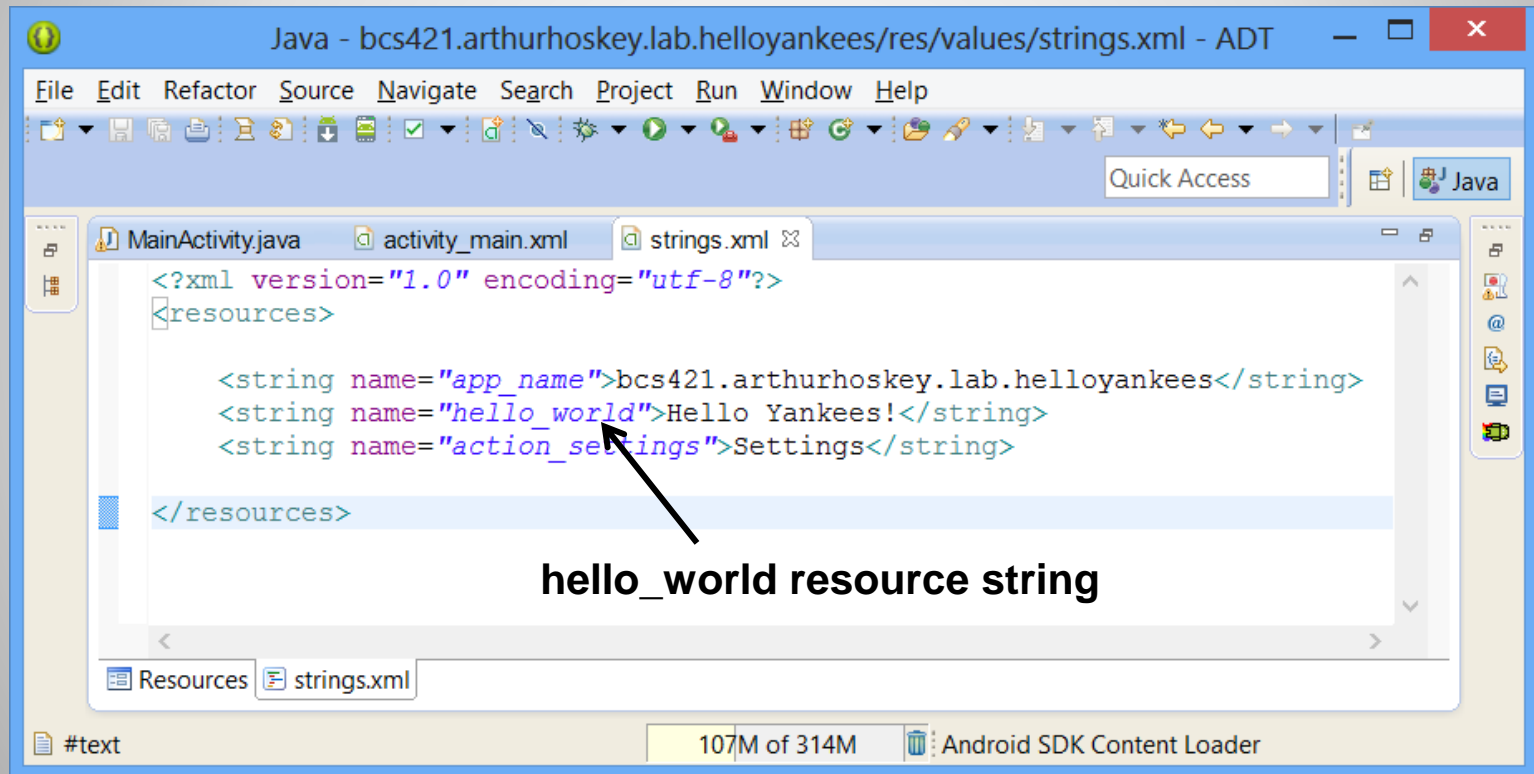

- Now on to string resources...

String Resources

- All strings should be defined in the string resource file(s).
- **Always use string resources.** When referencing a string resource in your application you should use the string resource id (do not hard code strings in your app).
- It is better to use string resources as opposed to hardcoding strings into your app.
- For example...

String Resources

- Here is a string resource file that defines a resource string named `hello_world`.
- The value of `hello_world` is "Hello Yankees!".

Define String Resources

- **Use string resource in composable code.**
- Use the **stringResource** function to access string resources in composable code.
- For example:

Use the string resource id to
get the string value

```
Text(text = stringResource(id = R.string.hello_world))
```

The Text element now has the value
of the hello_world string resource

Using String Resource in Composable

- **Use string resource in normal code.**
- Use the **getString** function to access strings in normal code.
- For example:

Use the string resource id to
get the string value

```
var s = getString(R.string.hello_world)
```

s now has the value of the
hello_world string resource

Note: getString is a method on the Context class.

Using String Resources in Code

- Resource id creation...

Resource Id Creation

R.txt

- **Generated automatically** based on external resources.
- Created when your project is compiled.
- Contains the definition of each resource.

R.txt

- The following XML code is from a strings.xml file.
- It defines two string resources:
 - app_name
 - hello_world
- When this project is compiled the R.txt file will contain variables for each of the string resources.

```
<?xml version="1.0" encoding="utf-8"?>  
<resources>
```

```
    <string name="app_name">bcs421.arthurhoskey.lab.helloyankees blah blah</string>  
    <string name="hello_world">Hello Yankees!</string>
```

```
</resources>
```

strings.xml

- This resource ids are defined in R.txt. R.txt is located in the subdirectory:
 \app\build\intermediates\runtime_symbol_list\debug
- **DO NOT EDIT THIS FILE**

- Here is some of the contents of an R.txt file:

```
int anim abc_fade_in 0x7f010000
int anim abc_fade_out 0x7f010001
int anim abc_grow_fade_in_from_bottom 0x7f010002
...
```

```
int string app_name 0x7f0f001c
...
int string hello_world 0x7f0f007c
...
```

resource name (hello_world)

hello_world unique resource id number

Resource type (string)

R.txt

```
Text(text = stringResource(id = R.string.hello_world))
```

R means
resource

Resource type

Resource id name

R.Txt File

```
int string hello_world 0x7f0f007c
```

Resource
type

Resource id
name

Resource
unique id
number

Using Resource ID

- Now on to using different languages and hardware...

Different Languages and Hardware

- You can also create different resources for the following:
 - Specific languages
 - Locations
 - Hardware configurations
- Use a parallel directory structure within the res folder.
- Each directory gets its own copy of the resource file.
- Good Localization Link:
<http://developer.android.com/guide/topics/resources/localization.html>
- For example...

Different Languages and Hardware

res/

values/

strings.xml

Default values folder. If no other folder matches then this one will be used.

values-fr/

strings.xml

French language value resources

values-fr-rCA/

strings.xml

French language for the region Canada

values-ja/

strings.xml

Japanese language value resources

values-en-rUS/

strings.xml

English language value resources for the region United States

values-en-rCA/

strings.xml

English language value resources for the region Canada

Different Languages and Hardware

- Android handles runtime changes to the following:
 - Language
 - Location
 - Hardware
- Android terminates and restarts the active Activity to do this.
- You can bypass this behavior
- You can detect and react to these changes yourself.
- Textbook gives details of this process.

Runtime Configuration Changes

- You can also create external resources for the following:
 - Colors
 - Dimensions
 - Styles and Themes
 - Drawables
 - Animations
 - Property Animations
 - View Animations
 - Frame-by-Frame Animations
- Usage and setup for these are similar to what we have seen.

Other Resource Types

- What is the benefit of externalizing resources?
- What folder are all resources stored in?
- What folder are the string resources stored in?
- How would you go about using different languages in an app?
